The Effect of Public-School Expenditure on Pupil's Performance

1. Introduction

Is public expenditure on education an economic priority? Globally, improving education quality ranks high on the 2030 Agenda for Sustainable Development (United Nations, 2015). In 2022, governments and households spent about US\$55 per school child in low-income countries, while donor countries contributed a record US\$16.6 billion to education in developing nations (World Bank, 2024). This analysis examines whether spending on education improves pupils' performance.

Economists have long studied this relationship, establishing the field of the economics of education. Human capital theory, a core framework, views education as an investment in human capital (Becker, 1962). It posits that investing in education develops the skills, knowledge, and competencies that boost individual and national productivity and earnings. Empirical evidence supports this view. Baron (2022) found that rising school spending by US\$1000 per student increased test scores by 8 percent and lowered dropout rates by 9 percent in poor districts of Wisconsin. Hyman (2017) showed that students in Michigan who benefited from a 10 percent increase in school funding were 7 percent more likely to go to college and 11 percent more likely to earn a degree. Krueger and Lindahl (2001) showed a strong positive and statistically significant effect of investing in

education on individual wages and economic growth.

The rest of the paper includes sections on descriptive statistics, data analysis and interpretation, further statistical and graphical tests, and a conclusion.

2. Descriptive Statistics

Table I below shows that the average test score of a pupil is 654 points, with the best pupil scoring 707 points and worst 606 points. The average expenditure per pupil per year in each district is US\$5,312. The maximum expenditure per pupil is US\$7,711 and the minimum is US\$3,926. The average district has an annual income of US\$15,317, with the poorest district having an income of US\$5,335 per year while the richest US\$55,328 per year. Some districts have 100 percent of their pupils receiving food vouchers while others have none. On average, each pupil has at least one computer. However, some pupils have no access to computers even though some schools have at least four computers per pupil. The average class has about 16 percent share of non-native English speakers but some schools zero number of non-native English speakers.

Table 1: Summary Statistics

	Mean	SD	Minimum	Maximum	Observations
Average Test Scores	654.1565	19.05335	605.55	706.75	420
Expenditures Per Pupil	5312.408	633.9371	3926.07	7711.507	420
Share of Pupils with Food Vouchers (in %)	44.70524	27.12338	0	100	420
Number of Computers Per Pupil	.1359266	.0649558	0	.4208333	420
Average Income (in 1000 US\$)	15.31659	7.22589	5.335	55.328	420
Share of Non-native English Speakers (in %)	15.76816	18.28593	0	85.53972	420

Figure I shows a histogram of the distribution of the average test scores. The shape is approximately symmetric, indicating that pupil's test scores are evenly distributed around the mean.

Figure I: The distribution of average test scores

Figure II below shows a histogram of the distribution of expenditure per pupil. The distribution is right-skewed, meaning expenditure per pupil is concentrated at lower values with a long tail toward higher spending levels.

Figure II: The distribution of school spending

Figure III below shows a scatter plot of the relationship between school expenditure and pupil's test scores. The correlation coefficient of

0.191 indicates a weak positive correlation, meaning that expenditure can indeed influence test scores.

Figure III: Relationship between school spending and pupils performance

3. Data Analysis and Interpretation

In this section, I applied OLS to estimate the effect of school spending on pupil's performance. I first defined a baseline model to guide the analysis below:

3.1. Baseline economic model

Average Test Scores = f (Expenditure Per Pupil, Covariates)

Performance in test scores, measured by the average test scores, is a function of public-school expenditure, measured by expenditure per pupil, plus other covariates, such as, school meals, access to a computer, income, and non-native English speakers in a class.

3.2. Econometric Model

$$y_i = \beta_0 + \beta_1 x_i + \gamma X_i + \varepsilon_i$$

Where: y_i is the dependent variable (average test scores); x is the independent variable (expenditure per pupil); X is a vector of covariates; and ϵ_i is the disturbance term, capturing unobserved factors. The coefficient of interest is β_1 because it captures the effect of public-school expenditure on pupil's performance. average test scores. Since governments and households, including donors, primarily invest in education to improve educational outcomes of pupils, the sign of β_1 is expected to be positive.

3.3. OLS Results

Table II presents the OLS estimates. Column (1) is a bivariate regression of pupil's average test scores on expenditure per pupil. The coefficient (29.465) indicates a positive and statistically significant effect. However, this analysis focuses on the interpretation of the multivariate results in column (2), which is in fact the baseline model. The main coefficient of interest, β_1 , is 8.906. It implies that a one percent increase in expenditure per pupil is associated with 0.089 points increase in pupil's average test scores, holding other factors constant. This is statistically significant at the 5% level ($p\text{-value} < 0.05$). On average, one percentage point increase in the share of non-native English speakers is associated with 0.187 points decrease in pupil's average test scores, ceteris paribus. This is significant at the 1% level. Increasing the number of computers per pupil by one computer on average increases pupil's average test scores by 13.9 points, ceteris paribus. Increasing annual income of the district by one dollar on average increases pupil's average test scores by 0.624 points, holding other factors

constant. This is also significant at the 1% level. Finally, one percentage point increase in the share of pupils with food vouchers is associated with a decrease of 0.406 points in pupil's average test scores, other factors constant. This is significant at the 1% level. The model explains about 81 percent of the variation in pupil's average test scores ($R_Squared = 0.808$) and is jointly significant ($F\text{-statistic } p\text{-value} < 0.001$). This result implies that public school expenditure does improve pupil's performance.

Table II: OLS results of average test scores on expenditure per pupil

	(1) Bivariate Regression	(2) Multivariate Regression
log of expenditure per pupil	29.465*** (8.008)	8.906** (4.016)
Share of non-native English speakers (in %)		-0.187*** (0.031)
Number of computers per pupil		13.887** (6.779)
Average income (in 1000 US\$)		0.624*** (0.088)
Share of pupils with food vouchers (in %)		-0.406*** (0.028)
Constant	401.607*** (68.642)	587.459*** (33.492)
F-Statistic	13.539	348.486
Prop > F	0.000	0.000
R-Squared	0.031	0.808
Adjusted R-squared	0.029	0.806
Observations	420	420

Standard errors in parentheses
* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

4. Functional Form and Model Testing

In this part, the analysis compares the baseline model with a log-linear model to ascertain which model specification is ideal for estimating the relationship between school spending and pupil performance. Table III presents the OLS estimates. Column (1) shows the baseline model and column (2) shows a log-linear model. The baseline model has a larger adjusted R-squared (0.806) than the log-linear model (0.798). In addition, it has a lower AIC (2985) and BIC (3009) as compared to the log-linear model. This means that the baseline model explains the relationship better than the log-linear model.

Table III: Comparing model specifications

	(1) Baseline Model	(2) Log-linear Model
log (expenditure per pupil)	8.906** (4.016)	11.735*** (4.030)
Share of non-native English speakers (in %)	0.187*** (0.031)	-0.168*** (0.032)
Number of computers per pupil	13.887** (6.779)	16.932** (6.913)
Average income (in 1000 US\$)	0.624*** (0.088)	0.798 (0.088)
Share of pupils with food vouchers (in %)	-0.406*** (0.028)	-0.410*** (0.031)
log (average income)		10.492*** (1.806)
Constant	587.459*** (33.492)	544.488*** (32.818)
Adjusted R-squared	0.806	0.798
AIC	2985.447	3001.159
BIC	3009.688	3025.400
Observations	420	420

Standard errors in parentheses
* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

5. Analysis of Heteroskedasticity.

This section presents a test for heteroskedasticity in the baseline model using white test and graphical approach.

5.1. White Test

Table IV presents the OLS estimates of the baseline model with and without robust standard errors and the p -value of the white test (0.734). Heteroskedasticity is rejected at the 5% level (white test p -value > 0.05). In column (2), estimating the baseline model with robust standard errors did not change the coefficients but did slightly change the standard errors. Thus, the baseline model is homoscedastic. That is, the explanatory variables are uncorrelated with the error term.

Table IV: OLS estimates with Robust SEs

	(1) OLS	(2) OLS with Robust SE
log (expenditure per pupil)	8.906** (4.016)	8.906** (4.257)
Share of non-native English speakers (in %)	-0.187*** (0.0313)	-0.187*** (0.0321)
Number of computers per pupil	13.89** (6.779)	13.89** (7.558)
Average income (in 1000 US\$)	0.624*** (0.0875)	0.624*** (0.0841)
Share of pupils with food vouchers (in %)	-0.406*** (0.0280)	-0.406*** (0.0299)
Constant	587.5*** (33.49)	587.5*** (35.53)
Observations	420	420
R-Squared	0.808	0.808
White Test p-value	0.734	0.734

Standard errors in parentheses
* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

5.2. Graphical Analysis of heteroskedasticity

Figure IV below presents a scatter plot of residuals against fitted values. The plot shows no distinct patterns, implying no evidence of heteroskedasticity. In addition, the lowess smooth line is approximately flat and centered around zero, which further suggests no evidence of heteroskedasticity.

Figure IV: Scatter plot of residuals and fitted values

6. Endogeneity

The above analysis reveals that public-school spending is positively associated with educational performance. Further tests of the baseline model reveals that it explains this relationship better. In addition, it is homoscedastic and has no omitted variables.

However, the estimated effect could possibly contain the effect of other unobserved factors such as parental education and income. Parental education is likely to have a positive correlation with both school spending and pupil performance, suggesting the OLS estimate of school expenditure may be upward biased. Parental

income is another unobserved factor that may positively correlate with both public spending and pupil performance. Rich parents are likely to spend more on their children's education, thus positively impacting their performance. In this case, the estimated coefficient of public-school expenditure is upward biased.

These factors rise a possibility of omitted variable bias and hence endogeneity issues which this study could not resolve. Therefore, future studies could explore the effect of these factors and or estimate causality using, for example, IV or other befitting identification methods.

7. Conclusion

This analysis examined whether public-school expenditure improves pupil performance. The main OLS estimate reveals a positive and significant association. Increasing expenditure per pupil by one percent is associated with 0.089 points increase in pupils' average test scores. Though the estimated model is well-specified and homoscedastic, there are concerns about endogeneity. This is because unobserved factors such as parental education and income may positively correlate with both expenditure per pupil and performance, and this renders the OLS estimate as upward biased. Nonetheless, this analysis provides suggestive evidence of a positive association between public school expenditure and pupil's performance.
